<p>8. Hrithik Joseph (223058217)</p>	<p>Build a predictive model for running duration</p>	<p>* Developed an Accurate Predictive Model for Running Duration</p> <p>I successfully built and implemented a robust regression model that predicts running duration using key input variables such as distance, elevation gain, and pace</p> <p>*Enhanced Model Reliability through Multi-Model Evaluation and Visualization</p> <p>I evaluated multiple machine learning algorithms—including Linear Regression, Ridge Regression, Random Forest, and Gradient Boosting—to identify the best performing model based on RMSE and <math>R^2</math></p>

		<p>metrics. I also created clear visualizations comparing actual and predicted durations, enhancing interpretability and actionable insights for the coaching team.</p>  <p>Model Evaluation Summary:  Linear Regression: RMSE = 537.89 seconds, <math>R^2 = 0.83</math>  Ridge Regression: RMSE = 537.89 seconds, <math>R^2 = 0.83</math>  Random Forest: RMSE = 320.06 seconds, <math>R^2 = 0.94</math>  Gradient Boosting: RMSE = 277.70 seconds, <math>R^2 = 0.96</math></p> <p>Actual vs Predicted Running Duration - Gradient Boosting</p> <p>The scatter plot shows Duration (Seconds) on the y-axis (1000 to 7000) versus Test Sample Index on the x-axis (0 to 30). It compares Actual Duration (blue dots) and Predicted Duration (Gradient Boosting) (orange dots). The predictions are very close to the actual values, indicating high model performance.</p>
9. Jeswin Joy (224832817)		<p>I loaded the dataset, standardised key columns, checked missing values, explored distributions, and flagged the outliers.</p> <p>I normalised the unit duration from hours to minutes and distance to kilometres, removed the duplicates and incomplete rows.</p> <p>I trained two baselines to predict duration in minutes: Linear Regression and Ridge with cross-validated regularisation in a scaling pipeline.</p> <p>I reported MAE, RMSE, and <math>R^2</math> and plotted predicted vs actual values.</p>  <p>Baseline: Predicted vs Actual (Ridge)</p> <p>The scatter plot shows Predicted duration (min) on the y-axis (0 to 400) versus Actual duration (min) on the x-axis (0 to 400). A dashed blue line represents the ideal prediction (y=x). The data points (blue dots) are tightly clustered around this line, showing a strong positive correlation between predicted and actual duration.</p>
10. Madhav Grover		
11. Nathan Riley	Progressed the predicting sleep efficiency using the sleep efficiency dataset	<p>Sleep Efficiency Prediction</p> <p>The sleep efficiency dataset tracks athletes and non-athletes sleep and rates the efficiency of that sleep</p>

	<p>(ongoing) Srihari and I working on our assigned task regarding documentation</p>	<p>by analysing metrics such as no. of exercises performed, alcohol consumed, duration, etc. Using models, I'm attempting to analyse and predict these ratings so it can be used as a tool for athletes to achieve the highest rating possible so it can lead to peak performance by maximising recovery. I have incorporated a couple new models, and having determined RF as the optimal model for the prediction, I'm at the concluding stages where I'm inputting new data which can hopefully strengthen the model after comparing it to some previous entries. I'll begin looking into new things I can target this week. The task with Srihari is ongoing with discussions still going as well.</p> <pre>Mean Absolute Error (MAE): 0.036 Root Mean Squared Error (RMSE): 0.048 R-squared (R^2): 0.874  upd_random_row = upd_columns.sample(n = 1)  print(upd_random_row)  Age  Gender  Sleep duration  REM sleep percentage  Deep sleep percentage  \ 195   61      0           7.0                23                23  Light sleep percentage  Awakenings  Caffeine consumption  \ 195                  54           2.0                50.0  Alcohol consumption  Smoking status  Exercise frequency 195                  5.0              0                0.0  # Create a Dataframe Prediction using: Age = 35, Coff Consumption = 100, Alc Consumption = 2, Ex Freq = 3 upd_rf_prediction = pd.DataFrame(upd_random_row, columns = upd_columns.columns)  # Predict sleep efficiency upd_predicted_eff = np.round(upd_best_rf.predict(upd_rf_prediction), 2)  print(upd_predicted_eff)  [0.66]</pre> <p>Once again we've gone through the process and fine tuned the RF model for predicting sleep efficiency. After running through the process of selecting a row at random and running the new prediction through the updated Random Forest model, we were given a predicted Sleep Efficiency rating of 0.66. Upon inspection of the table, we go to row 197 (195 + 1 + 1 since the row count starts at 0 and we account for title row) and see the actual Sleep Efficiency rating is 0.67.</p> <p>A difference of 0.01 is closer again and therefore are even more satisfied with this model when it comes to predictions. We can try inputting our own variables for a prediction or can even try building a model that predicts sleep duration or sleep efficiency based on a couple of variables alone.</p>
12. Saumya Parasbhai	Perform cross validations on datasets	<p>Cricket Performance Prediction</p> <p>developed and evaluated a number of prediction models that use batting characteristics like balls faced, strike rate, boundaries, and sixes to estimate the number of runs scored. Five-fold cross-validation was used for KNN, Random Forest, and Linear Regression. With the lowest mean absolute error and the highest R2 score, the results demonstrated that Linear Regression consistently performed better than the others. This demonstrated that the model was dependable for analyzing cricket performance since runs scored were well clarified by linear relationships between batting inputs and results.</p>

		<p>Linear Regression: MAE: 3.061183925144868 R²: 0.976829429446577</p> <p>Random Forest: MAE: 3.543338476198476 R²: 0.9494681834358297</p> <p>KNN: MAE: 4.62 R²: 0.9313317847861667</p> <p>Model Comparison with 5-Fold Cross Validation</p> <div> <p>Average MAE (Lower is Better)</p> <p>Average R² (Higher is Better)</p> </div> <p>VO<sub>2</sub> Max Prediction</p> <p>Using physiological and training data from Garmin, a cross-validated regression model was developed to forecast athletes' VO<sub>2</sub> Max values. With a high R2 and a low mean absolute error across folds, the Random Forest model showed good predictive power. Consistent model stability was validated by visualizing fold-wise results, suggesting that the model performs well when applied to athlete data that has not yet been seen. The possibility of using wearable data to track physical activity and provide data-driven performance insights is confirmed by these findings.</p> <p>Average MAE: 0.8772196318482095 Average R²: 0.9241144974941177</p> <p>K-Fold Cross-Validation Results - VO<sub>2</sub> Max Prediction</p>
<p>13. Scott Ailaiti (224348919)</p>	<p>Exploratory Data Analysis (EDA)</p> <p>Data Cleaning &amp; Preprocessing</p> <p>Feature Engineering</p> <p>Data Transformation (Normalization &amp; Encoding)</p>	<p>I contributed to the data preprocessing pipeline by performing essential cleaning and transformation tasks on the provided running dataset. My responsibilities included loading and previewing the data, checking and confirming the absence of missing values, and removing duplicate rows and extreme outliers (e.g., heart rates above 250 bpm) to ensure data quality. I also implemented a time conversion function that transformed "Duration (h:m:s)" and "Moving Duration (h:m:s)" columns into total seconds to facilitate accurate numerical analysis. These foundational steps laid the</p>

14. Siddh Parashbai	<div>Perform Cross Validation on the datasets and get insights.</div>	<div>An end-to-end machine learning pipeline was created to forecast the aerobic capacity (VO<sub>2</sub>max) of cyclists based on power output data from 20-kilometer time trials. With an R2 of -0.52, the model showed low efficacy, failing to capture significant physiological correlations between VO<sub>2</sub>max and cycling performance. The limited physiological range of VO<sub>2</sub>max values (3.0-6.0 ml/kg/min) concealed basic model flaws, even with numerically minor mistakes (MAE: 0.76 ml/kg/min). The main failure point identified by permutation importance analysis was insufficient feature representation, underscoring the necessity of including extra physiological indicators such as heart rate variability, cadence patterns, and individual anthropometric data in order to establish reliable power-to-VO<sub>2</sub>max relationships for precise fitness evaluation.</div>																																																																																										

		<div data-bbox="869 206 1082 264" data-label="Text"> <p>Prediction for VO<sub>2</sub>max (ml/kg/min):  Average R<sup>2</sup>: -0.52  Average MAE: 0.76  Average RMSE: 0.90</p> </div> <div data-bbox="869 268 1452 672" data-label="Figure"> </div> <div data-bbox="798 678 1516 1370" data-label="Text"> <p>created a predictive system that uses power output measurements to estimate the heart rate response in real time during cycling time trials. With clinically relevant error margins (MAE: 7.33 bpm) and moderate explanatory power (R<sup>2</sup>: 0.39), the model captured fundamental patterns of exertion but lacked individual precision. Power output fluctuations were found to be the main driver by feature importance analysis, which also revealed significant gaps in the accounting for environmental components and cumulative fatigue effects. The methodology has promise for monitoring coarse exertion in training scenarios; nevertheless, in order to attain actionable accuracy for performance optimization, temporal factors such as acute:chronic workload ratios, temperature acclimatization measurements, and individual recovery patterns must be integrated.</p> </div> <div data-bbox="869 1377 1050 1435" data-label="Text"> <p>Prediction for Heart Rate (bpm):  Average R<sup>2</sup>: 0.39  Average MAE: 7.33  Average RMSE: 8.21</p> </div> <div data-bbox="869 1440 1399 1809" data-label="Figure"> </div>

Here is the activity intensity distribution by minutes portrayed in a boxplot:

Here is the correlation matrix between all related variable/metrics

Based on the summary statistics and distribution, we have created the following activity profiles: Highly Active, Moderately Active, Balanced, Lightly Active and Sedentary. Here is the adjusted distribution visualised through bar chart.

		<p>Distribution of Activity Profiles</p> <table><tr><th>Activity_Profile</th><th>Count</th></tr><tr><td>Highly Active</td><td>112</td></tr><tr><td>Moderately Active</td><td>108</td></tr><tr><td>Balanced</td><td>15</td></tr><tr><td>Lightly Active</td><td>513</td></tr><tr><td>Sedentary</td><td>115</td></tr></table>	Activity_Profile	Count	Highly Active	112	Moderately Active	108	Balanced	15	Lightly Active	513	Sedentary	115
Activity_Profile	Count													
Highly Active	112													
Moderately Active	108													
Balanced	15													
Lightly Active	513													
Sedentary	115
